

Early Journal Content on JSTOR, Free to Anyone in the World

This article is one of nearly 500,000 scholarly works digitized and made freely available to everyone in the world by JSTOR.

Known as the Early Journal Content, this set of works include research articles, news, letters, and other writings published in more than 200 of the oldest leading academic journals. The works date from the mid-seventeenth to the early twentieth centuries.

We encourage people to read and share the Early Journal Content openly and to tell others that this resource exists. People may post this content online or redistribute in any way for non-commercial purposes.

JSTOR is a digital library of academic journals, books, and primary source objects. JSTOR helps people discover, use, and build upon a wide range of content through a powerful research and teaching platform, and preserves this content for future generations. JSTOR is part of ITHAKA, a not-for-profit organization that also includes Ithaka S+R and Portico. For more information about JSTOR, please contact support@jstor.org.

III. *An Account of an Experiment touching the Direction of a Drop of Oil of Oranges, between two Glasſs Planes, towards any ſide of them that is neareſt preſs'd together. By Mr. Fr. Hauksbee, F. R. S.*

THE Glasſs Planes which I uſed were about 6 Inches ſquare; and being very clean, a drop or two of Oil of Oranges was let fall on the lower Plane, ſuppoſe at B; then the upper Plane was laid on it, ſo near as to touch the Liquid, that it might become Contiguous

to both their Surfaces. Thus the Planes being made to touch one another at the ſide A, and opened at the ſide C, as in the Scheme above, the lower Plane lying parallel with the Horizon, the drop of Oil would immediately move towards the touching ſide of the Planes; and when it was arrived there, it was but reverſing the Angle, and the Drop would return from A to C; and after the ſame Manner it might be directed to any ſide or part of the ſame. Moreover, if the Planes were elevated 8 or 10 Degrees at A, yet would the Drop aſcend towards the ſide A, tho' not ſo ſwift as when the Planes were in the fore-mentioned Poſition. It was farther to be obſerved, that the nearer the Drop approach'd the touching ſide, ſo would the Velocity of its Motion be encreaſed: The reaſon of which ſeems very

very plain, allowing the Ascent of Water in small Tubes, and between the Surfaces of nearly contiguous Planes, to be explain'd from the Power of Attraction, that one Surface has to another at such a nearness (as I see no Reason to doubt it :) For the Drop of Oil moving on towards the contiguous Surfaces, comes to enlarge its space, and touches the Planes in more and more Parts, as it approaches nearer and nearer the touching side. Thus in the whole Progress of its Motion, it is continually encreasing in its Surface, and consequently the Power of Attraction must encrease in proportion to that Surface ; so that the Celerity of its Motion must necessarily be augmented. This Experiment seems very powerfully to confirm the Experiments made before on the same Subject, from the gradual Increase of the Motion of the Drop ; representing thereby the several Appearances of the Ascent of Water in different siz'd Tubes, or between Planes whose Surfaces are placed at different distances, the slower Motion representing those Experiments made in larger, and the swifter in smaller Tubes ; the same to be observed in different distanc'd Planes.

I have since repeated the same Experiment *in vacuo*, where, in all Respects, it answered as in the open Air ; which is a plain Indication, that the Presence of the Air has nothing at all to do in producing this *Phenomenon*.
